

BD401 / 6702 - Beam Switching Noise Generator

Burroughs BD401, registered as 6702, was a non-conventional vacuum tube intended to operate as wide-band random noise generator. It was introduced quite late, in 1964, derived from magnetic beam switched counters, removing all but two spade and grid electrode pairs, so to introduce asymmetries of the already undulated electric field inside. Basically it takes advantage from the random noise generated in a magnetron-like device operated near cutoff and also into an asymmetric electric field distribution. 6702 was registered together with its Beam-X new style version, the [BX1203/6713](#). Probably its production was secret for a while, before registration.

BD401 was specified for 0.08 mW minimum noise in the range between 200 and 400 megahertz.

6.3 volts heater.

RMA release record [4599](#). For operation of trochotron tubes also see this [article](#).
